it is well known that the traditional failure criteria cannot adequately explain failures which occur at a nominal stress level considerably lower than the ultimate strength of the material the current procedure for predicting the safe loads or safe useful life of a structural member has been evolved around the discipline of linear fracture mechanics this approach introduces the concept of a crack extension force which can be used to rank materials in some order of fracture resistance the idea is to determine the largest crack that a material will tolerate without failure laboratory methods for characterizing the fracture toughness of many engineering materials are now available while these test data are useful for providing some rough guidance in the choice of materials it is not clear how they could be used in the design of a structure the understanding of the relationship between laboratory tests and fracture design of structures is to say the least deficient fracture mechanics is presently at a standstill until the basic problems of scaling from laboratory models to full size structures and mixed mode crack propagation are resolved the answers to these questions require some basic understanding of the theory and will not be found by testing more specimens the current theory of fracture is inadequate for many reasons first of all it can only treat idealized problems where the applied load must be directed normal to the crack plane

this monograph focuses on the numerical methods needed in the context of developing a reliable simulation tool to promote the use of renewable energy one very promising source of energy is the heat stored in the earth's crust which is harnessed by so called geothermal facilities scientists from fields like geology geo engineering geophysics and especially geomathematics are called upon to help make geothermics a reliable and safe energy production method one of the challenges they face involves modeling the mechanical stresses at work in a reservoir the aim of this thesis is to develop a numerical solution scheme by means of which the fluid pressure and rock stresses in a geothermal reservoir can be determined prior to well drilling and during production for this purpose the method should i include poroelastic effects ii provide a means of including thermoelastic effects iii be inexpensive in terms of memory and computational power and iv be flexible with regard to the locations of data points after introducing the basic equations and their relations to more familiar ones the heat equation stokes equations cauchy navier equation the method of fundamental solutions and its potential value concerning our task are discussed based on the properties of the fundamental solutions theoretical results are established and numerical examples of stress field simulations are presented to assess the method's performance the first ever 3d graphics calculated for these topics which neither requiring meshing of the domain nor involving a time stepping scheme make this a pioneering volume
