the present study has been accepted as a doctoral thesis by the department of economics of the Johann Wolfgang Goethe University in Frankfurt am Main. It grew out from my five year long participation in two research projects: econometric analysis of transaction intensity and volatility on financial markets and microstructure on financial markets that were both conducted by the Chair of Statistics and Econometrics, Empirical Economic Research at the Department of Economics and Business Administration, Johann Wolfgang Goethe University in Frankfurt am Main and financed by the State of Hessen. During this time I have benefitted from many people. First and foremost I would like to thank my thesis supervisor Prof. Dr. Reinhard Hujer for initiating and supporting my studies with great encouragement. I am also very grateful to Prof. Dr. Christian Schlag for acting as the second thesis supervisor. Furthermore I wish to thank Prof. Dr. Joachim Grammig who introduced me to the topics covered in this study in the first place and helped me to sharpen my views on econometrics and financial market microstructure theory through many discussions and also through his willingness to work with me on several related studies.

Modelling has permeated virtually all areas of industrial, environmental, economic, bio-medical or civil engineering. Yet the use of models for decision making raises a number of issues to which this book is dedicated. How uncertain is my model? Is it truly valuable to support decision making? What kind of decision can be truly supported and how can I handle residual uncertainty? How much refined should the mathematical description be given the true data limitations? Could the uncertainty be reduced through more data, increased modeling investment or computational budget? Should it be reduced now or later? How robust is the analysis or the computational methods involved? Should those methods be more robust? Does it make sense to handle uncertainty, risk, lack of knowledge, variability or errors altogether? How reasonable is the choice of probabilistic modeling for rare events? How rare are the events to be considered? How far does it make sense to handle extreme events and elaborate confidence figures? Can I take advantage of expert phenomenological knowledge to tighten the probabilistic figures? Are there connected domains that could provide models or inspiration for my problem? Written by a leader at the crossroads of industry, academia and engineering and based on decades of multi-disciplinary field experience, *Modelling under Risk and Uncertainty* gives a self-consistent introduction to the methods involved by any type of modeling. Development acknowledging the inevitable uncertainty and associated risks, it goes beyond the black box view that some analysts, modelers, risk experts or statisticians develop on the underlying phenomenology of the environmental or industrial processes without valuing enough their physical properties and inner modelling potential nor challenging the practical plausibility of mathematical hypotheses. Conversely, it is also to attract environmental or engineering modellers to better handle model confidence issues through finer statistical and risk analysis material, taking advantage of advanced scientific computing to face new regulations, departing from deterministic design or support robust decision making. *Modelling under Risk and Uncertainty* addresses a concern of growing interest for large industries, environmentalists or analysts: robust modeling for decision making in complex systems gives new insights into the peculiar mathematical and computational challenges generated by recent industrial safety or environmental control analysis for rare events, implements decision theory choices differentiating or aggregating the dimensions of risk: aleatory and epistemic uncertainty through a consistent multi-disciplinary set of statistical estimation, physical modelling, robust computation.

today understanding turbulence is one of the key issues in tackling flow problems in engineering powerful computers and numerical methods are now available for solving flow equations but the simulation of turbulence effects which are nearly always important in practice are still at an early stage of development successful simulation of turbulence requires the understanding of the complex physical phenomena involved and suitable models for describing the turbulence momentum heat and mass transfer the 89 papers including 5 invited papers in this volume present and discuss new developments in the area of turbulence modelling and measurements with particular emphasis on engineering related problems the high standard of the contributions on the developing and testing of turbulent models attests to the world wide interest this domain is currently attracting from researchers

over the past decade we have made great advances in the field of multiple sclerosis ms research and this book focuses on those advances in ms pathogenesis and treatment while some of these advances have been through new approaches and ideas that have emerged in the last decade such as the newly identified protective role that amyloid proteins may play in ms or the use of helminths to treat autoimmune diseases others have evolved from previous theories and ideas that have only now gained momentum and a deeper understanding such as the role of hla or gender in ms susceptibility this book covers these emerging and evolving topics and highlights the substantial advancements made in elucidation of the factors regulating susceptibility or disease progression identification of new ways to monitor or predict ms pathology and development of new strategies for treating ms

our topic is irreversible or plastic deformation of structural elements composed of relatively thin ductile materials these deformations are commonly used in sheet metal forming operations to produce lightweight parts of any particular shape in another context this type of plastic deformation is described as impact damage in

the case of structural components involved in collision here we are concerned with mechanics of both static and dynamic deformation processes the purpose is to use typical material properties and structural characteristics to calculate the deformation for certain types of load in particular to find the final deflection and shape of the deformed structure and to illustrate how the development of this final shape depends on the constitutive model used to represent the material behavior the major issue to be addressed is which structural and constitutive properties are important for calculating response to either static or brief but intense dynamic loads furthermore how do the results of various constitutive models compare with observed behavior

for centuries physical models have been used to investigate complex hydraulic problems leonardo da vinci 1452 1519 stated i will treat of such a subject but first of all i shall make a few experiments and then demonstrate why bodies are forced to act in this matter even with the current advancements of mathematical numerical models certain complex three dimensional flow phenomena must still rely on physical model studies mathematical models cannot provide adequate solutions if physical processes involved are not completely known physical models are particularly attractive to investigate phenomena involved sediment movements because many three dimensional sediment processes are still unclear at this stage theoretically there are numerous factors governing movable bed processes and it is nearly impossible to design model studies to obey all the model criteria sometimes appropriate lightweight materials are difficult or too costly to obtain often distorted models are used due to the limitation of available space and the requirement for greater vertical flow depth to investigate vertical differences of various parameters

the turbulence level in the model may also be maintained at a sufficient level to reproduce a similar flow pattern in the prototype frequently engineers are forced to employ distorted models that cannot be designed to satisfy all governing criteria correctly thus each hydraulic laboratory has developed its own rules for model testing and a great deal of experience is needed to interpret model results
