basalt is the most voluminous of all the igneous rocks extensive field experimental petrographic and geochemical studies of basalt have provided us with a considerable understanding of igneous petrogenesis plate tectonics and crust mantle interaction and exchange one important aspect of geology that has developed over the last few decades is the study of oceanic basalts the ocean basins cover about two thirds of the earth s surface and are floored by a basement of oceanic basalt that is continuously undergoing generation at spreading centres and destruction at subduction zones a process which throughout geological time is recognized as the principal means of generating new crust the study of oceanic basalts enables us to understand better the generation and recycling of crustal materials including the continental crust and the exchange between oceanic crust and seawater via hydrothermal activity compositional variations displayed by oceanic basalts provide windows into the mantle and the identification of isotopically distinct mantle reservoirs demonstrates that the source of oceanic basalts is heterogeneous and is controlled by convection and reservoir interactions within the mantle

the variations of electromagnetic field components along a line across central california have been examined in the frequency range 125 to 4 cph by means of an array of stations extending from 320 km inland to 630 km offshore the three components of the magnetic variations were recorded at six land positions simultaneously records of the oceanic electric field in a direction approximately parallel to the coast were obtained at three stations located as far as 150 km offshore by using self contained recorders installed on the sea floor the cross correlation of all field components leads to field relationships suggesting a large scale nearly two dimensional structure of the electrical conductivity of the earth's crust and upper mantle in a region adjacent to the california coast estimates of the continental and oceanic conductivity distribution with depth were carried out by solving numerical models the estimate of the offshore conductivity profile based on models of the coastal cross section are in excellent agreement with the independent magnetotelluric sounding in the light of the present knowledge of the properties of rocks at high pressure and temperature the high electrical conductivity of the oceanic basement favors a highly basaltic external mantle shell extending to no less than 30 km below the mohorovicic discontinuity author

some empirical relations between diffusion characteristics are investigated by the use of carefully examined data from dye release experiments in the surface layer of the sea these data cover a time scale of diffusion ranging from 1 hour to 1 month and a length scale from 100 m to 100 km two oceanic diffusion diagrams are prepared one showing horizontal variance versus diffusion time and the other showing apparent diffusivity versus the scale of diffusion the overall behaviors of the horizontal variance and of the apparent diffusivity are evidently different from those which the similarity theory of turbulence deduces however there still remains a possibility that the similarity theory may be valid locally in time or length scale with a variable parameter i e the rate of turbulent energy transfer the diagrams provide a practical means to predict the rate of horizontal spread of substance introduced from an instantaneous point source as well as the apparent diffusivity as a function of the size of diffusing patch
