it is over a quarter of a century since the discovery of outflows from young stars the intervening years have led to remarkable advances in our understanding of this phenomenon much of the progress can be attributed to advances in facilities and technologies including not

only larger telescopes but also improved instrument and detector performance in addition protostellar out flows have now been imaged from the ground and space at high spatial resolution e.g. with HST and at a wide variety of wavelengths from X-rays to radio waves revealing more and more about their physics. This veritable revolution in observation has been accompanied by an exponential growth in our ability to numerically simulate the launching and propagation of jets. Codes continue to improve; they now incorporate more physics and are increasingly efficient through techniques such as adaptive mesh refinement and the use of parallel processing in cluster environments. Simulating the launching and propagation of a jet all the way from the vicinity of the star up to several thousand AU at a size range of 10^4 is now much closer to what can be achieved in observation. Theory and numerical simulation have been joined by laboratory jet experiments reproducing on centimetre scales what is seen in astrophysics to stretch for several parsecs.
